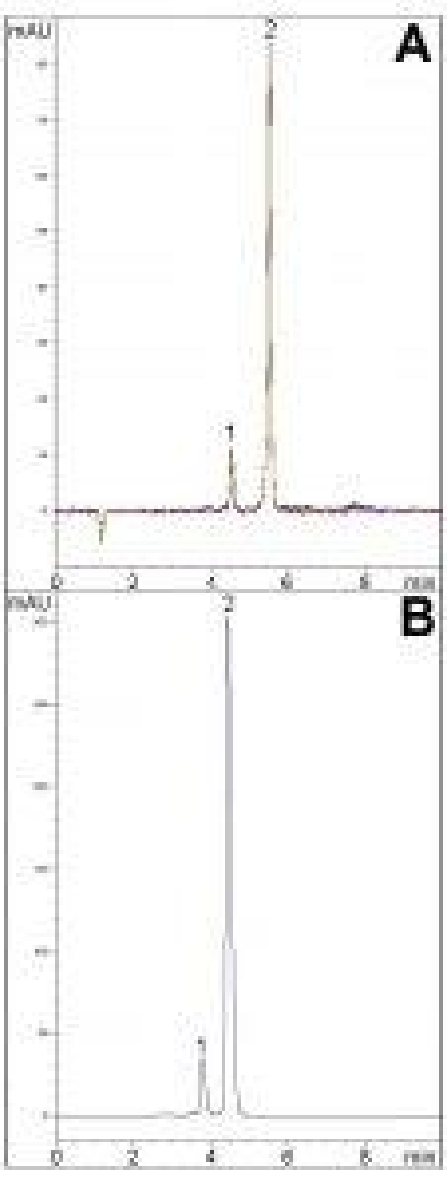
Levothyroxine Analysis - AppNote

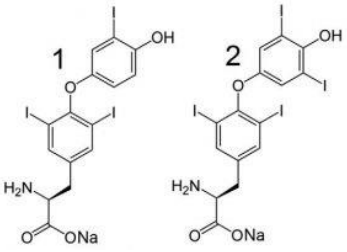
Superior Resolution, Reproducibility, & Peak Shapes Compared to USP Method

Click *HERE* for Column Ordering Information.

The USP assay method for Levothyroxine requires that a resolution of not less than 5.0 must be demonstrated between Levothyroxine and related compound Liothyronine. A chromatogram obtained from following the USP method using a Type-B Silica based L10 Column is shown in *Figure B*.

The average resolution between the two compounds over five runs is 2.8, which does not satisfy the system suitability for resolution for this assay. *Figure A* shows the five-run overlay obtained from a method developed with the Cogent Phenyl Hydride Column. The average resolution in this case was 5.3.





Peaks:

1. Liothyronine Sodium
2. Levothyroxine Sodium

Method Conditions

Columns:

Fig. B: 1.5 mL / minutes

Sample Preparation: Mix of Levothyroxine and Liothyronine standards.

Stock Solution: 0.4 mg Levothyroxine or Liothyronine dissolved with 1 mL 10 mM NaOH in 50:50 DI Water: Methanol.

Working Solution: *Fig. A:* Aliquots of stock solutions were mixed and diluted with 50:50 A:B to obtain concentrations of 40 mg / L and 4 mg / L for Levothyroxine and Liothyronine respectively.

Working Solution: *Fig. B:* Aliquots of stock solutions were mixed and diluted with the Mobile Phase to obtain concentrations of 10 mg /L and 0.2 mg / L for Levothyroxine and Liothyronine respectively.

Note: *Levothyroxine is the L-isomer of the main thyroid hormone Thyroxine (T4). It is used as a replacement for the Thyroxine that is deficient in patients with hypothyroidism. Liothyronine* is the L-isomer of another thyroid hormone, Triiodothyronine (T3). T3 is produced from T4 and is the metabolically active form of the hormone.
